Abstract

In this paper we consider the asymptotic distributions of functionals of the sample covariance matrix and the sample mean vector obtained under the assumption that the matrix of observations has a matrix variate general skew normal distribution. The central limit theorem is derived for the product of the sample covariance matrix and the sample mean vector. Moreover, we consider the product of an inverse covariance matrix and the mean vector for which the central limit theorem is established as well. All results are obtained under the large dimensional asymptotic regime where the dimension $p$ and sample size $n$ approach to infinity such that $p/n \to c \in (0,1)$.

ASM Classification: 62H10, 62E15, 62E20, 60F05, 60B20

Keywords: Skew normal distribution, large dimensional asymptotics, stochastic representation, random matrix theory.

1 Introduction

In our work we introduce the family of matrix variate general skew normal (MVGSN) distributions which is a generalization of the models considered by Azzalini and Dalla-Valle (1996), Azzalini and Capitanio (1999), Azzalini (2005), Liseo and Loperfido (2003, 2006), Bartoletti and Loperfido (2010), Loperfido (2010), Christiansen and Loperfido (2014), Adcock et al. (2015), De Luca and Loperfido (2015) and among others. Under the assumption of MVGSN we consider the expressions for the sample mean vector $\mathbf{x}$ and the sample covariance matrix $\mathbf{S}$. In particular, we deal with two products $\mathbf{l}^T \mathbf{S} \mathbf{x}$ and $\mathbf{l}^T \mathbf{S}^{-1} \mathbf{x}$ where $\mathbf{l}$ is a non-zero vector of constants. It is noted that this kind of expressions has not been intensively considered in the literature, although they are present in numerous important applications. The first application of the products arises in the portfolio theory, where the vector of optimal portfolio weights is proportional to $\mathbf{S}^{-1} \mathbf{x}$. The second application is in the discriminant analysis where the coefficients of the discriminant function are expressed as a product of the inverse sample covariance matrix and the difference of the sample mean vectors. In Bayesian context it is highly related to the product $\mathbf{S} \mathbf{x}$.

Bodnar and Okhrin (2011) derived the exact distribution of the product of the inverse sample covariance matrix and the sample mean vector under the assumption of normality, while Kotsiuba and Mazur (2015) obtained its asymptotic distribution as well as its approximate density based on the Gaussian integral and the third order Taylor series expansion. Moreover, Bodnar et al. (2013, 2014b) analyzed the product of the sample (singular) covariance matrix and the sample mean vector. In the present paper, we contribute to the existing literature by deriving the central limit theorems (CLTs) under the introduced class of matrix variate distribution, i.e., general matrix variate skew normality in the case of the high-dimensional observation matrix. Under the considered family of distributions, the columns of the observation matrix are not independent anymore and, thus, the CLTs cover more general class of random matrices.

Nowadays, modern scientific data include large number of sample points which is often
comparable to the number of features (dimension) and so the sample covariance matrix and 
the sample mean vector are not the efficient estimators anymore. For example, stock markets 
include a large number of companies which is often close to the number of available time points. 
In order to understand better the statistical properties of the traditional estimators and tests 
based on high-dimensional settings, it is of interest to study the asymptotic distribution of the 
above mentioned bilinear forms involving the sample covariance matrix and the sample mean 
vector.

The appropriate central limit theorems, which do not suffer from the “curse of dimension-
ality” and do not reduce the number of dimensions, are of great interest for high-dimensional 
statistics because more efficient estimators and tests may be constructed and applied in practice. 
The classical multivariate procedures are based on the central limit theorems assuming that the 
dimension $p$ is fixed and the sample size $n$ increases. However, numerous authors provide quite 
reasonable proofs that this assumption does not lead to precise distributional approximations for 
commonly used statistics, and that under increasing dimension asymptotics the better approxi-
mations can be obtained [see, e.g., Bai and Silverstein (2004) and references therein]. Technically 
speaking, under the high-dimensional asymptotics we understand the case when the sample size 
$n$ and the dimension $p$ tend to infinity, such that their ratio $p/n$ converges to some positive 
constant $c$ (here we assume that $c < 1$). Under this condition the well-known Marchenko-Pastur 
and Silverstein’s equations were derived [see, Marčenko and Pastur (1967), Silverstein (1995)].

The rest of the paper is structured as follows. In Section 2 we introduce a semi-parametric 
matrix-variate family of skewed distributions. Main results are given in Section 3, where we 
derive the central limit theorems under high-dimensional asymptotic regime of the sample (in-
verse) covariance matrix and the sample mean vector under the MVGSN distribution. Section 
4 presents a short numerical study in order to verify the obtained analytic results.

2 Semi-parametric matrix-variate family of skewed distributions

In this section we introduce a family of matrix-variate skewed distributions which generalizes 
the skew normal distribution.

Let

$$
X = \begin{pmatrix}
    x_{11} & \ldots & x_{1n} \\
    \vdots & \ddots & \vdots \\
    x_{p1} & \ldots & x_{pn}
\end{pmatrix} = (x_1, \ldots, x_n),
$$
be the \( p \times n \) observation matrix where \( x_j \) is the \( j^{th} \) observation vector. In the following, we assume that the random matrix \( X \) possesses a stochastic representation given by

\[
X \overset{d}{=} Y + B\nu 1_n^T, \tag{1}
\]

where \( Y \sim N_{p,n}(\mu 1_n^T, \Sigma \otimes I_n) \) (\( p \times n \)-dimensional matrix-variate normal distribution with mean matrix \( \mu 1_n^T \) and covariance matrix \( \Sigma \otimes I_n \)), \( \nu \) is a \( q \)-dimensional random vector with continuous density function \( f_\nu(\cdot) \), \( B \) is a \( p \times q \) matrix of constants. Further, it is assumed that \( Y \) and \( \nu \) are independently distributed. If random matrix \( X \) follows model (1) then we say that \( X \) is generalized matrix-variate skew-normal distributed with parameters \( \mu, \Sigma, B, \) and \( f_\nu(\cdot). \) The first three parameters are finite dimensional, while the third parameter is infinite dimensional. This makes model (1) to be of a semi-parametric type. The assertion we denote by \( X \sim SN_{p,n,q}(\mu, \Sigma, B; f_\nu) \). If \( f_\nu \) can be parametrized by finite dimensional parameter \( \theta \) then model (1) reduces to a parametrical model which is denoted by \( X \sim SN_{p,n,q}(\mu, \Sigma, B; \theta) \). If \( n = 1 \) then we use the notation \( SN_{p,q}(\cdot, \cdot, \cdot) \) instead of \( SN_{p,1,q}(\cdot, \cdot, \cdot) \).

From (1) the density function of \( X \) is expressed as

\[
f_X(Z) = \int_{\mathbb{R}^q} f_{N_{p,n}(\mu, \Sigma \otimes I_n)}(Z - B\nu 1_n^T|\nu = \nu^*)f_\nu(\nu^*)d\nu^*. \tag{2}
\]

Let \( C = \Phi_q(0; -\xi, \Omega) \). In a special case when \( \nu = |\psi| \) is the vector formed by the absolute values of every element in \( \psi \) where \( \psi \sim N_q(\xi, \Omega), \) i.e. \( \nu \) has a \( q \)-variate truncated normal distribution, we get

**Proposition 1.** Assume model (1). Let \( \nu = |\psi| \) with \( \psi \sim N_q(\xi, \Omega). \) Then the density function of \( X \) is given by

\[
f_X(Z) = \tilde{C}^{-1}\Phi_q(0; -D|\text{vec}(Z - \mu 1_n^T) + \Omega^{-1}\xi|, D) \phi_{pn}(\text{vec}(Z - \mu 1_n^T); FE^T\Omega^{-1}\xi, F) \tag{3}
\]

where \( D = (nB^T\Sigma^{-1}B + \Omega^{-1})^{-1} \), \( E = 1_n^T \otimes B^T\Sigma^{-1} \), \( F = (I_n \otimes \Sigma^{-1} - E^TDE)^{-1} \), and

\[
\tilde{C}^{-1} = C^{-1}\frac{1}{|\Omega|^{n/2}}\frac{1}{|\Sigma|^{n/2}}\exp\left\{ -\frac{1}{2}[\xi^T\Omega^{-1}(D + \Omega - DEE^TDE)^{-1}\xi]\right\}.
\]

The proof of Proposition 1 is presented in the Appendix.

It is remarkable that model (1) includes several skew-normal distributions considered by Azzalini and Dalla-Valle (1996), Azzalini and Capitanio (1999), Azzalini (2005). For example,
in case of \( n = 1, q = 1, \mu = 0, B = \Delta 1_p, \) and \( \Sigma = (I_p - \Delta^2)^{1/2} \Psi (I_p - \Delta^2)^{1/2} \) we get

\[
X \overset{d}{=} (I_p - \Delta^2)^{1/2} v_0 + \Delta 1_p |v_1|, \tag{4}
\]

where \( v_0 \sim \mathcal{N}_p(0, \Psi) \) and \( v_1 \sim \mathcal{N}(0, 1) \) are independently distributed; \( \Psi \) is a correlation matrix and \( \Delta = \text{diag}(\delta_1, ..., \delta_p) \) with \( \delta_j \in (-1, 1) \). Model (4) was previously introduced by Azzalini (2005).

3 CLTs for expressions involving the sample covariance matrix and the sample mean vector

The sample estimators for the mean vector and the covariance matrix are given by

\[
\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i = \frac{1}{n} X 1_n \quad \text{and} \quad S = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x}) (x_i - \bar{x})^T = XVX^T,
\]

where \( V = I_n - \frac{1}{n} 1_n 1_n^T \) is a symmetric idempotent matrix, i.e., \( V = V^T \) and \( V^2 = V \).

The following theorem shows that \( \bar{x} \) and \( S \) are independently distributed and presents their marginal distributions under model (1). The results of Theorem 1 show that the independence of \( \bar{x} \) and \( S \) could not be used as a characterization property of a multivariate normal distribution if the observation vectors in data matrix are dependent.

**Theorem 1.** Let \( X \sim SN_{p,n,q}(\mu, \Sigma, B; f_\nu) \) with \( p < n - 1 \). Then

(a) \((n-1)S \sim W_p(n-1, \Sigma) \) (\( p \)-dimensional Wishart distribution with \( n-1 \) degrees of freedom and covariance matrix \( \Sigma \)),

(b) \( \bar{x} \sim SN_{p,q}(\mu, \frac{1}{n} \Sigma, B; f_\nu) \),

(c) \( S \) and \( \bar{x} \) are independently distributed.

**Proof.** Let \( X^* \overset{d}{=} X|\nu = \nu^* \), \( \bar{x}^* \overset{d}{=} \bar{x}|\nu = \nu^* \), and \( S^* \overset{d}{=} S|\nu = \nu^* \). Because \( Y \) and \( \nu \) are independent we get that

\[
X^* \overset{d}{=} X|\nu = \nu^* \sim \mathcal{N}_{p,n}((\mu + B \nu^*) 1_n^T, \Sigma \otimes I_n).
\]
From Theorem 3.1.2 of Muirhead (1982) we obtain that

$$\mathbf{x}^* \sim \mathcal{N}_p \left( \mu + B\nu^*, \frac{1}{n} \Sigma \right),$$

$$S^* \sim \mathcal{W}_p(n-1, \Sigma)$$

and \( S^* \) and \( \mathbf{x}^* \) are independent. Hence, it follows that

$$f_{\mathbf{x}, S}(\tilde{x}, \tilde{S}) = \int_{\mathbb{R}_+^p} f_{S|\nu=\nu^*}(\tilde{S}) f_{\mathbf{x}|\nu=\nu^*}(\tilde{x}) f_{\nu}(\nu^*) \, d\nu^*$$

where the last equality follows from the fact that the density of \( S^* \) does not depend on \( \nu^* \).

From (5) we directly get that \( \mathbf{x} \) and \( S \) are independent; \( S \) is Wishart distributed with \((n-1)\) degrees of freedom and covariance matrix \( \Sigma \); \( \mathbf{x} \) is generalized skew-normal distributed with parameters \( \mu, \frac{1}{n} \Sigma, B \) and \( f_{\nu} \). The theorem is proved.

For the validity of the asymptotic results presented in Sections 3.1 and 3.2 we need the following two conditions

(A1) Let \((\lambda_i, \mathbf{u}_i)\) denote the set of eigenvalues and eigenvectors of \( \Sigma \). We assume that there exist \( m_1 \) and \( M_1 \) such that

$$0 < m_1 \leq \lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_p \leq M_1 < \infty$$

uniformly on \( p \).

(A2) There exists \( M_2 \) such that

$$|\mathbf{u}_i^T \mu| \leq M_2 \quad \text{and} \quad |\mathbf{u}_i^T \mathbf{b}_j| \leq M_2 \quad \text{for all} \quad i = 1, \ldots, p \quad \text{and} \quad j = 1, \ldots, q$$

uniformly on \( p \) where \( \mathbf{b}_j, \ j = 1, \ldots, q \), are the columns of \( \mathbf{B} \).

In more general terms, we say that an arbitrary \( p \)-dimensional vector \( \mathbf{l} \) satisfies the condition (A2) if \( |\mathbf{u}_i^T \mathbf{l}| \leq M_2 \) for all \( i = 1, \ldots, p \).

Assumption (A1) is a classical condition in random matrix theory (see, Bai and Silverstein (2004)), which bounds the spectrum of \( \Sigma \) from below as well as from above. Assumption (A2) is a technical one. In combination with (A1) this condition ensures that \( p^{-1} \mu^T \Sigma \mu, p^{-1} \mu^T \Sigma^{-1} \mu, p^{-1} \mu^T \Sigma^3 \mu, p^{-1} \mu^T \Sigma^{-3} \mu \), as well as that all the diagonal elements of \( \mathbf{B}^T \Sigma \mathbf{B}, \mathbf{B}^T \Sigma^3 \mathbf{B}, \) and
$B^T \Sigma^{-1} B$ are uniformly bounded. All these quadratic forms are used in the statements and the proofs of our results. Note that the constants appearing in the inequalities will be denoted by $M_2$ and may vary from one expression to another.

### 3.1 CLT for the product of sample covariance matrix and sample mean vector

In this section we present the central limit theorem for the product of the sample covariance matrix and the sample mean vector.

**Theorem 2.** Assume $X \sim SN_{p,n}(\mu, \Sigma, B; f\nu)$, $p < n - 1$, with $\Sigma$ positive definite and let $p/n = c + o(n^{-1/2})$, $c \in [0,1)$ as $n \to \infty$. Let $1$ be a $p$-dimensional vector of constants that satisfies condition (A2). Then, under (A1) and (A2) it holds that

$$\sqrt{n} \sigma_{\nu}^{-1} \left(1^T S x - 1^T \Sigma \mu_{\nu}\right) \xrightarrow{D} N(0,1) \quad \text{for } p/n \to c \in [0,1) \quad \text{as } n \to \infty,$$

where

$$\mu_{\nu} = \mu + B\nu,$$

$$\sigma_{\nu}^2 = [\mu_{\nu}^T \Sigma \mu_{\nu} + c||\Sigma||^2_F] 1^T \Sigma 1 + (1^T \Sigma \mu_{\nu})^2.$$

**Proof.** Since $S$ and $x$ are independently distributed, the conditional distribution $1^T S x | (x = x^*)$ equals to the distribution of $1^T S x^*$. Let $L^* = (1, x^*)^T$ and define $\tilde{S} = L^* S L^T = \{\tilde{S}_{ij}\}_{i,j=1,2}$ with $\tilde{S}_{11} = 1^T S 1$, $\tilde{S}_{12} = 1^T S x^*$, $\tilde{S}_{21} = x^T S 1$, and $\tilde{S}_{22} = x^T S x^*$. Similarly, let $\tilde{\Sigma} = L^* \Sigma L^T = \{\tilde{\Sigma}_{ij}\}_{i,j=1,2}$ with $\tilde{\Sigma}_{11} = 1^T \Sigma 1$, $\tilde{\Sigma}_{12} = 1^T \Sigma x^*$, $\tilde{\Sigma}_{21} = x^T \Sigma 1$, and $\tilde{\Sigma}_{22} = x^T \Sigma x^*$.

Using $S \sim W_p \left(n - 1, \frac{1}{n - 1} \Sigma\right)$ and rank $L^* = 2 \leq p$ we get from Theorem 3.2.5 of Muirhead (1982) that $\tilde{S} \sim W_2 \left(n - 1, \frac{1}{n - 1} \Sigma\right)$. As a result, applying Theorem 3.2.10 of Muirhead (1982) we obtain

$$\tilde{S}_{12} | \tilde{S}_{22}, \bar{x} = x^* \sim N_k \left(\frac{\tilde{\Sigma}_{12} \tilde{\Sigma}_{22}^{-1} \tilde{S}_{22}}{n - 1} \tilde{\Sigma}_{11:2}, \frac{1}{n - 1} \tilde{\Sigma}_{11:2} \tilde{S}_{22}\right),$$

where $\tilde{\Sigma}_{11:2} = \tilde{\Sigma}_{11} - \tilde{\Sigma}_{12}^2/\tilde{S}_{22}$ is the Schur complement.

Let $\xi = (n - 1) \tilde{S}_{22} / \tilde{S}_{22}$, then

$$1^T S x | \xi, \bar{x} \sim N \left(\frac{\xi}{n - 1} 1^T \Sigma x, \frac{\xi}{(n - 1)^2} [\Sigma^T \Sigma x] \Sigma 1 - (\Sigma^T \Sigma 1)^2\right).$$

From Theorem 3.2.8 of Muirhead (1982) follows that $\xi$ and $\bar{x}$ are independently distributed.
and $\xi \sim \chi^2_n$. Hence, the stochastic representation of $l^T S x$ is given by

$$l^T S x \sim \mathcal{N}(0, \Sigma),$$

where $\xi \sim \chi^2_n$, $z_0 \sim \mathcal{N}(0, 1)$, $\mathbf{x} \sim \mathcal{N}(\mu, \frac{1}{n} \Sigma, B; f \nu)$; $\xi$, $z_0$ and $\mathbf{x}$ are mutually independent.

From the properties of $\chi^2$-distribution we immediately receive $\sqrt{n} (\frac{\xi}{n} - 1) \xrightarrow{d} \mathcal{N}(0, 2)$ as $n \to \infty$.

We further get that $\sqrt{n} \left( \frac{z_0}{\sqrt{n}} \right) \sim \mathcal{N}(0, 1)$ for all $n$ and, consequently, it is also its asymptotic distribution.

Next, we show that $l^T \Sigma x$ and $\mathbf{x}^T \Sigma \mathbf{x}$ are jointly asymptotically normally distributed given $\nu = \nu^*$. For any $a_1$ and $a_2$, we consider

$$a_1 \mathbf{x}^T \Sigma \mathbf{x} + 2a_2 l^T \Sigma \mathbf{x} = a_1 \left( \mathbf{x} + \frac{a_2}{a_1} l \right)^T \Sigma \left( \mathbf{x} + \frac{a_2}{a_1} l \right) - \frac{a_2^2}{a_1} l^T \Sigma l = a_1 \mathbf{x}^T \Sigma \mathbf{x} - \frac{a_2^2}{a_1} l^T \Sigma l,$$

where $\mathbf{x} | \nu = \nu^* \sim \mathcal{N}(\mu_{\mathbf{x}, \nu^*}, \frac{1}{n} \Sigma)$ with $\mu_{\mathbf{x}, \nu^*} = \mu + B \nu^* + \frac{a_2}{a_1} l$. By Provost and Rudinuk (1996) the random variable $\mathbf{x}^T \Sigma \mathbf{x}$ can be expressed as

$$\mathbf{x}^T \Sigma \mathbf{x} \overset{d}{\sim} \frac{1}{n} \sum_{i=1}^{p} \lambda_i^2 \xi_i,$$

where

$$\xi_i \overset{i.i.d.}{\sim} \chi^2_d(\delta_i^2)$$

with $\delta_i = \sqrt{n} \lambda_i^{-1/2} u_i^T \mu_{\mathbf{x}, \nu^*}$.

The symbol $\chi^2_d(\delta_i^2)$ denotes the chi-squared distribution with $d$ degrees of freedom and non-centrality parameter $\delta_i^2$.

Now, we use the Lindeberg CLT to the i.i.d. random variables $V_i = \lambda_i^2 \xi_i / n$. For that reason, we need first to verify the Lindeberg’s condition. Denoting $\sigma_n^2 = \mathbb{V}(\sum_{i=1}^{p} V_i)$ we get

$$\sigma_n^2 = \sum_{i=1}^{p} \mathbb{V} \left( \frac{\lambda_i^2}{n} \xi_i \right) = \sum_{i=1}^{p} \frac{\lambda_i^4}{n^2} 2(1 + 2 \delta_i^2) = \frac{1}{n^2} \left( 2\text{tr}(\Sigma^4) + 4n \mu_{\mathbf{x}, \nu^*} \Sigma^3 \mu_{\mathbf{x}, \nu^*} \right)$$

(11)

We need to check if for any small $\varepsilon > 0$ it holds that

$$\lim_{n \to \infty} \frac{1}{\sigma_n^2} \sum_{i=1}^{p} \mathbb{E} \left[ (V_i - \mathbb{E}(V_i))^2 1_{(|V_i - \mathbb{E}(V_i)| > \varepsilon \sigma_n)} \right] \to 0.$$
First, we get

\[
\sum_{i=1}^{p} \mathbb{E} \left[ (V_i - \mathbb{E}(V_i))^2 I_{\{|V_i - \mathbb{E}(V_i)| > \varepsilon \sigma_n \}} \right] \leq \sum_{i=1}^{p} \mathbb{E}^{1/2} \left[ (V_i - \mathbb{E}(V_i))^4 \right] \mathbb{E}^{1/2} \left[ |V_i - \mathbb{E}(V_i)| > \varepsilon \sigma_n \right]
\]

Chebyshev

\[
\leq \sum_{i=1}^{p} \frac{\lambda_i^4}{n^2} \sqrt{12(1 + 2\delta_i^2)^2 + 48(1 + 4\delta_i^2) \frac{\sigma_i}{\varepsilon \sigma_n}}
\]

with \( \sigma_i = \mathbb{V}(V_i) \) and, thus,

\[
\frac{1}{\sigma_n^2} \sum_{i=1}^{p} \mathbb{E} \left[ (V_i - \mathbb{E}(V_i))^2 I_{\{|V_i - \mathbb{E}(V_i)| > \varepsilon \sigma_n \}} \right] \leq \frac{1}{\varepsilon} \frac{\sum_{i=1}^{p} \lambda_i^4 \sqrt{12(1 + 2\delta_i^2)^2 + 48(1 + 4\delta_i^2) \frac{\sigma_i}{\varepsilon \sigma_n}}}{2 \text{tr} \left( \Sigma^4 \right) + 4n \mu_{a, \nu} \Sigma^3 \mu_{a, \nu}}
\]

\[
= \frac{\sqrt{3} \sum_{i=1}^{p} \lambda_i^4 \sqrt{(5 + 2\delta_i^2)^2 - 20 \frac{\sigma_i}{\sigma_n}}}{\varepsilon \text{tr} \left( \Sigma^4 \right) + 2n \mu_{a, \nu}^T \Sigma^3 \mu_{a, \nu}}
\]

\[
\leq \frac{\sqrt{3}}{\varepsilon} \left( \frac{4}{1 + 2n \mu_{a, \nu}^T \Sigma^3 \mu_{a, \nu} \text{tr} \left( \Sigma^4 \right)} + 1 \right) \frac{\sigma_{\max}}{\sigma_n}
\]

\[
\leq \frac{5 \sqrt{3} \sigma_{\max}}{\varepsilon} \frac{\sigma_n}{\sigma_n}
\]

Finally, Assumptions (A1) and (A2) yield

\[
\frac{\sigma_{\max}^2}{\sigma_n^2} = \frac{\sup_i \sigma_i^2}{\sigma_n^2} = \frac{\sup_i \lambda_i^4 (1 + 2\delta_i^2)}{\text{tr} \left( \Sigma^4 \right) + 2n \mu_{a, \nu}^T \Sigma^3 \mu_{a, \nu}} = \frac{\sup_i \lambda_i^4 + 2n \lambda_i^3 \left( u_i^T \mu_{a, \nu} \right)^2}{\text{tr} \left( \Sigma^4 \right) + 2n \mu_{a, \nu}^T \Sigma^3 \mu_{a, \nu}} \rightarrow 0,
\]

which verifies the Lindeberg condition since

\[
(u_i^T \mu_{a, \nu})^2 = \left( u_i^T \mu + u_i^T \mathbf{B} \nu + u_i^T \frac{\alpha_2}{a_1} \right)^2
\]

\[
= (u_i^T \mu)^2 + \left( u_i^T \frac{\alpha_2}{a_1} \right)^2 + (u_i^T \mathbf{B} \nu)^2 + 2u_i^T \mu \cdot u_i^T \mathbf{B} \nu + 2u_i^T \nu \cdot u_i^T \mu + 2u_i^T \nu \cdot u_i^T \frac{\alpha_2}{a_1}
\]

\[
\overset{(A2)}{\leq} M_2^2 + q M_2^2 \nu^T \nu + 2 M_2^2 \frac{\alpha_2}{a_1} + 2 M_2^2 \sqrt{q \nu^T \nu} + 2 M_2^2 \frac{\alpha_2}{a_1} (1 + \sqrt{q \nu^T \nu})
\]

\[
= M_2^2 \left( 1 + \sqrt{q \nu^T \nu} + \frac{\alpha_2}{a_1} \right)^2 < \infty.
\]

Thus, using (11) and

\[
\sum_{i=1}^{p} \mathbb{E}(V_i) = \sum_{i=1}^{p} \frac{\lambda_i^2}{n} (1 + \delta_i^2) = \text{tr} \left( \Sigma^2 \right) / n + \mu_{a, \nu}^T \Sigma \mu_{a, \nu}.
\]
we get the following CLT
\[
\sqrt{n} \left( \bar{x}^T \Sigma \bar{x} - \frac{\text{tr}(\Sigma^2)}{n} - \mu_{\bar{a}, \nu}^T \Sigma \mu_{\bar{a}, \nu} \right) \frac{d}{\sqrt{\text{tr}(\Sigma^4)/n + 2\mu_{\bar{a}, \nu}^T \Sigma^3 \mu_{\bar{a}, \nu}}} \to \mathcal{N}(0, 2)
\]
and for \( a_1 \bar{x}^T \Sigma \bar{x} + 2a_2 I^T \Sigma \bar{x} \) we have
\[
\sqrt{n} \left( a_1 \bar{x}^T \Sigma \bar{x} + 2a_2 I^T \Sigma \bar{x} - a_1 \left( \frac{\text{tr}(\Sigma^2)}{n} + \mu_{\bar{a}, \nu}^T \Sigma \mu_{\bar{a}, \nu} \right) + \frac{a_2^2}{a_1} I^T \Sigma I \right) \frac{d}{\sqrt{\frac{a_1^2}{a_1} \left( \frac{\text{tr}(\Sigma^4)}{n} + 2\mu_{\bar{a}, \nu}^T \Sigma^3 \mu_{\bar{a}, \nu} \right)}} \to \mathcal{N}(0, 2).
\]
Denoting \( a = (a_1, 2a_2)^T \) and \( \mu_{\nu}^* = \mu + Bu^* \) we can rewrite it as
\[
\sqrt{n} \left[ a^T \begin{pmatrix} (\bar{x}^T \Sigma \bar{x}) - a_1 \left( \mu_{\bar{a}, \nu}^T \Sigma \mu_{\bar{a}, \nu} + c\frac{\text{tr}(\Sigma^2)}{n} \right) \end{pmatrix} \right] \to \mathcal{N}(0, a^T \begin{pmatrix} 2c \frac{\text{tr}(\Sigma^2)}{n} + 4\mu_{\nu}^T \Sigma^3 \mu_{\nu} \end{pmatrix}) \tag{15}
\]
which implies that the vector \( \sqrt{n} \left( \bar{x}^T \Sigma \bar{x} - \mu_{\nu}^T \Sigma \mu_{\nu}^* - c\frac{\text{tr}(\Sigma^2)}{n}, I^T \Sigma \bar{x} - I^T \Sigma \mu_{\nu}^* \right)^T \) has asymptotically multivariate normal distribution because the vector \( a \) is arbitrary.

Taking into account (15), (10) and the fact that \( \xi, z_0 \) and \( \bar{x} \) are mutually independent we get the following CLT
\[
\sqrt{n} \left[ \begin{pmatrix} \xi \bar{x}^T \Sigma \bar{x} \\ \bar{x}^T \Sigma \bar{x} / n \end{pmatrix} \right] \to \mathcal{N}(0, \begin{pmatrix} 2 & 0 & 0 & 0 \\ 0 & 2c \frac{\text{tr}(\Sigma^2)}{n} + 4\mu_{\nu}^T \Sigma^3 \mu_{\nu} & 2I^T \Sigma^3 \mu_{\nu} & 0 \\ 0 & 2I^T \Sigma^3 \mu_{\nu} & 1I^T \Sigma^4 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}).
\]
The application of the multivariate delta method leads to
\[
\sqrt{n} \sigma_{\nu}^{-1} (I^T \Sigma \bar{x} - I^T \Sigma \mu_{\nu}) \frac{d}{\mathcal{N}(0, 1)} \tag{16}
\]
where
\[
\sigma_{\nu}^2 = (I^T \Sigma \mu_{\nu})^2 + I^T \Sigma I \left[ \mu_{\nu}^T \Sigma \mu_{\nu} + c\frac{\text{tr}(\Sigma^2)}{n} \right]
\]
The asymptotic distribution does not depend on \( \nu^* \) and, thus, it is also the unconditional asymptotic distribution.

Theorem 2 shows that properly normalized bilinear form \( I^T \Sigma \bar{x} \) itself can be accurately approximated by a mixture of normal distributions with both mean and variance depending on \( \nu \). Moreover, this central limit theorem delivers the following approximation for the distribution of
\( \mathbf{1}^T \mathbf{S} \mathbf{x} \), namely for large \( n \) and \( p \) we have

\[
p^{-1} \mathbf{1}^T \mathbf{S} \mathbf{x} \approx \mathcal{CN} \left( p^{-1} \mathbf{1}^T \Sigma \mu_\nu, \frac{p^{-2} \sigma_\nu^2}{n} \right),
\]

i.e., it has compound normal distribution with random mean and variance. The usual asymptotic normality can be recovered as a special case of our result, i.e., taking \( \nu \) as a deterministic vector (e.g., zero).

The proof of Theorem 2 shows, in particular, that its key point is a stochastic representation of the product \( \mathbf{1}^T \mathbf{S} \mathbf{x} \) which can be presented using a \( \chi^2 \) distributed random variable, a standard normally distributed random variable, and the random vector which follows the generalized skew normal distribution. Assumption (A1) ensures that the spectrum of matrix \( \Sigma \) is uniformly bounded away from zero, i.e., maximum eigenvalue is bounded from above and minimum eigenvalue from below by positive constants. The second assumption (A2) is a technical one, it stands, in particular, for boundedness of normalized Frobenius norm of the population covariance matrix. Both (A1) and (A2) guarantee that the asymptotic mean \( p^{-1} \mathbf{1}^T \Sigma \mu_\nu \) and variance \( p^{-2} \sigma_\nu^2 \) stay bounded and the covariance matrix \( \Sigma \) is invertible as the dimension \( p \) increases. Note that the case of standard asymptotics can be easily recovered from our result if we set \( c \to 0 \).

### 3.2 CLT for the product of inverse sample covariance matrix and sample mean vector

In this section we consider the distributional properties of the product of the inverse sample covariance matrix \( \mathbf{S}^{-1} \) and the sample mean vector \( \mathbf{x} \). Again we prove that proper weighted bilinear forms involving \( \mathbf{S}^{-1} \) and \( \mathbf{x} \) have asymptotically a normal distribution. This result is summarized in Theorem 3.

**Theorem 3.** Assume \( \mathbf{X} \sim SN_{p,n,q}(\mu, \Sigma, \mathbf{B}; f_\nu) \), \( p < n - 1 \), with \( \Sigma \) positive definite and let \( p/n = c + o(n^{-1/2}) \), \( c \in [0, 1) \) as \( n \to \infty \). Let \( \mathbf{l} \) be a \( p \)-dimensional vector of constants such that \( p^{-1} \mathbf{l}^T \Sigma^{-1} \mathbf{l} \leq M_2 < \infty \). Then, under (A1) and (A2) it holds that

\[
\sqrt{n} \tilde{\sigma}_\nu^{-1} \left( \mathbf{1}^T \mathbf{S}^{-1} \mathbf{x} - \frac{1}{1 - c} \mathbf{1}^T \Sigma^{-1} \mu_\nu \right) \overset{D}{\to} N(0,1)
\]

where \( \mu_\nu = \mu + \mathbf{B} \nu \) and

\[
\tilde{\sigma}_\nu^2 = \frac{1}{(1 - c)^3} \left( (\mathbf{1}^T \Sigma^{-1} \mu_\nu)^2 + \mathbf{1}^T \Sigma^{-1} \mathbf{1}(1 + \mu_\nu^T \Sigma^{-1} \mu_\nu) \right).
\]
Proof. From the properties of the Wishart distribution (see Muirhead (1982)) and Theorem 1 it holds that

\[ S^{-1} \sim IW_p \left( n + p, (n - 1) \Sigma^{-1} \right). \]

Since \( S^{-1} \) and \( \bar{x} \) are independently distributed we get that the conditional distribution of \( I^T S^{-1} \bar{x} | x = x^* \) equals to the distribution of \( I^T S^{-1} x^* \) with

\[ I^T S^{-1} x^* = (n - 1) \bar{x}^T \Sigma^{-1} x^* \frac{I^T S^{-1} x^*}{\bar{x}^T S^{-1} x^*} \frac{\bar{x}^T S^{-1} \bar{x}}{(n - 1) \bar{x}^T S^{-1} x^*}. \]

Using Theorem 3.2.12 of Muirhead (1982) we get that

\[ (n - 1) \frac{\bar{x}^T S^{-1} x^*}{\bar{x}^T S^{-1} x^*} \sim \chi^2_{n-p} \]

and it is independent of \( x^* \). Hence,

\[ \tilde{\xi} = (n - 1) \frac{\bar{x}^T S^{-1} \bar{x}}{\bar{x}^T S^{-1} x^*} \sim \chi^2_{n-p} \quad (19) \]

and it is independent of \( \bar{x} \).

Applying Theorem 3 of Bodnar and Okhrin (2008) it follows that \( \bar{x}^* S^{-1} x^* \) is independent of \( I^T S^{-1} \bar{x} / \bar{x}^T S^{-1} x^* \) for given \( \bar{x}^* \). Moreover, as a result, it is also independent of \( \bar{x}^* S^{-1} x^* \). \( I^T S^{-1} \bar{x} / \bar{x}^T S^{-1} x^* \) and, respectively, of \( \bar{x}^T \Sigma^{-1} \bar{x} \cdot I^T S^{-1} \bar{x} / \bar{x}^T S^{-1} x^* \).

From the proof of Theorem 1 of Bodnar and Schmid (2008) we obtain

\[ (n - 1) \frac{\bar{x}^T \Sigma^{-1} \bar{x}^*}{\bar{x}^T S^{-1} \bar{x}} \sim t \left( n - p + 1; (n - 1)I^T \Sigma^{-1} x^*; (n - 1)^2 \frac{\bar{x}^T \Sigma^{-1} x^*}{n - p + 1} I^T R_x 1 \right), \quad (20) \]

where \( R_a = \Sigma^{-1} - \Sigma^{-1} a a^T \Sigma^{-1} a^T / a^T \Sigma^{-1} a, a \in \mathbb{R}^p \), and the symbol \( t(k, \mu, \sigma^2) \) denotes \( t \) distribution with \( k \) degrees of freedom, mean \( \mu \) and variance \( \sigma^2 \).

Combining (19) and (20), we get that the stochastic representation of \( I^T S^{-1} x^* \) is given by

\[ I^T S^{-1} x^* \overset{d}{=} \frac{\tilde{\xi}}{\chi^2_{n-p}} (n - 1) \left( I^T \Sigma^{-1} x^* + t_0 \sqrt{\frac{\bar{x}^T \Sigma^{-1} x^*}{n - p + 1} I^T R_x 1} \right), \]

where \( \tilde{\xi} \sim \mathcal{N} \left( \mu + B \nu^*, \frac{1}{n} \Sigma \right), \tilde{\xi} \sim \chi^2_{n-p}, \) and \( t_0 \sim t(n - p + 1, 0, 1); \tilde{\xi}, x^* \) and \( t_0 \) are mutually independent.
Since $R_1 \Sigma R_1 = R_1$, $tr(R_1 \Sigma) = p - 1$, and $R_1 \Sigma^{-1} = 0$, the application of Corollary 5.1.3a and Theorem 5.5.1 in Mathai and Provost (1992) leads to

$$1^T \Sigma^{-1} \tilde{x}^* \sim N\left(1^T \Sigma^{-1}(\mu + B \nu^*), \frac{1}{n}1^T \Sigma^{-1}1\right)$$

and

$$x^T R_1 x^* \sim \chi^2_{p-1}(n \delta^2(\nu^*)) \text{ with } \delta^2(\nu^*) = (\mu + B \nu^*)^T R_1 (\mu + B \nu^*)$$

as well as $1^T \Sigma^{-1} \tilde{x}^*$ and $x^T R_1 x^*$ are independent. Finally, using the stochastic representation of a $t$-distributed random variable, we get

$$1^T S^{-1} x^* \overset{d}{=} \tilde{\xi}^{-1}(n - 1) \left(1^T \Sigma^{-1}(\mu + B \nu^*) + \sqrt{1^T \Sigma^{-1}1} \sqrt{1 + \frac{p-1}{n-p+1} \eta^* z_0 / \sqrt{n}}\right), \quad (21)$$

where $\tilde{\xi} \sim \chi^2_{n-p}$, $z_0 \sim N(0, 1)$, and $\eta^* \sim F_{p-1,n-p+1}(n \delta^2(\nu^*))$ (non-central $F$-distribution with $p - 1$ and $n - p + 1$ degrees of freedom and non-centrality parameter $n \delta^2(\nu^*)$); $\tilde{\xi}$, $z_0$ and $\eta^*$ are mutually independent.

From Lemma 6.4.(b) in Bodnar et al. (2016b) we get

$$\sqrt{n} \begin{pmatrix} \tilde{\xi}/(n-p) \\ \eta^* \\ z_0/\sqrt{n} \end{pmatrix} - \begin{pmatrix} 1 \\ 1 + \delta^2(\nu^*)/c \\ 0 \end{pmatrix} \overset{d}{\rightarrow} N\left(0, \begin{pmatrix} 2/(1-c) & 0 & 0 \\ 0 & \sigma^2_\eta & 0 \\ 0 & 0 & 1 \end{pmatrix}\right)$$

for $p/n = c + o(n^{-1/2})$, $c \in (0, 1)$ as $n \rightarrow \infty$ with

$$\sigma^2_\eta = \frac{2}{c} \left(1 + 2 \frac{\delta^2(\nu^*)}{c}\right) + \frac{2}{1-c} \left(1 + \frac{\delta^2(\nu^*)}{c}\right)^2$$

Consequently,

$$\sqrt{n} \begin{pmatrix} \tilde{\xi}/(n-1) \\ (p-1)\eta^*/(n-p+1) \\ z_0/\sqrt{n} \end{pmatrix} - \begin{pmatrix} (1-c) \\ (c + \delta^2(\nu^*))/(1-c) \\ 0 \end{pmatrix} \overset{d}{\rightarrow} N\left(0, \begin{pmatrix} 2(1-c) & 0 & 0 \\ 0 & c^2 \sigma^2_\eta/(1-c)^2 & 0 \\ 0 & 0 & 1 \end{pmatrix}\right)$$

for $p/n = c + o(n^{-1/2})$, $c \in (0, 1)$ as $n \rightarrow \infty$. 

13
Finally, the application of the delta-method (c.f. DasGupta (2008, Theorem 3.7)) leads to

$$\sqrt{n} \left( \mathbf{1}^T \mathbf{S}^{-1} \mathbf{x}^* - \frac{1}{1-c} \mathbf{1}^T \Sigma^{-1} (\mu + \mathbf{B} \nu^*) \right) \xrightarrow{D} \mathcal{N}(0, \tilde{\sigma}^2_{\nu^*})$$

for $p/n = c + o(n^{-1/2})$, $c \in (0, 1)$ as $n \to \infty$ with

$$\tilde{\sigma}^2_{\nu^*} = \frac{1}{(1-c)^2} \left( 2 \left( \mathbf{1}^T \Sigma^{-1} (\mu + \mathbf{B} \nu^*) \right)^2 + \mathbf{1}^T \Sigma^{-1} \mathbf{1} (1 + \delta^2(\nu^*)) \right).$$

Consequently,

$$\sqrt{n} \tilde{\sigma}^{-1}_{\nu^*} \left( \mathbf{1}^T \mathbf{S}^{-1} \mathbf{x}^* - \frac{1}{1-c} \mathbf{1}^T \Sigma^{-1} (\mu + \mathbf{B} \nu^*) \right) \xrightarrow{D} \mathcal{N}(0, 1),$$

where the asymptotic distribution does not depend on $\nu^*$. Hence, it is also the unconditional asymptotic distribution.

Again, Theorem 3 shows that the distribution of $\mathbf{1}^T \mathbf{S}^{-1} \mathbf{x}$ can be approximated by a mixture of normal distributions. Indeed,

$$p^{-1} \mathbf{1}^T \mathbf{S}^{-1} \mathbf{x} \approx \mathcal{CN} \left( \frac{p^{-1}}{1-c} \mathbf{1}^T \Sigma^{-1} \mu_{\nu^*}, \frac{p^{-2} \tilde{\sigma}^2_{\nu}}{n} \right). \quad (22)$$

In the proof of Theorem 3 we can read out that the stochastic representation for the product of the inverse sample covariance matrix and the sample mean vector is presented by using a $\chi^2$ distributed random variable, a general skew normally distributed random vector and a standard $t$-distributed random variable. This result is itself very useful and allows to generate the values of $\mathbf{1}^T \mathbf{S}^{-1} \mathbf{x}$ by just generating three random variables from the standard univariate distributions and a random vector $\nu$ which determines the family of the skew normal matrix variate distribution.

The assumptions about the boundedness of the quadratic and bilinear forms involving $\Sigma^{-1}$ plays here the same role as in Theorem 2. Note that in this case we need no assumption either on the Frobenius norm of the covariance matrix or its inverse.

## 4 Numerical study

In this section we provide a Monte Carlo simulation study to investigate the performance of the suggested CLTs for the products of the sample (inverse) covariance matrix and the sample mean vector.
In our simulations we put $l = 1_p$, each element of the vector $\mu$ is uniformly distributed on $[-1, 1]$ while each element of the matrix $B$ is uniformly distributed on $[0, 1]$. Also, we take $\Sigma$ as a diagonal matrix where each diagonal element is uniformly distributed on $[0, 1]$. It can be checked that in such a setting the assumptions (A1) and (A2) are satisfied. Indeed, the population covariance matrix satisfies the condition (A1) because the probability of getting exactly zero eigenvalue equals to zero. On the other hand, the condition (A2) is obviously valid too because the $i$th eigenvector of $\Sigma$ is $u_i = e_i = (0, \ldots, 1_{\text{ith place}}, 0, \ldots, 0)'$.

In order to define the distribution for the random vector $\nu$, we consider two special cases. In the first case we take $\nu = |\psi|$, where $\psi \sim N_q(0, I_q)$, i.e. $\nu$ has a $q$-variate truncated normal distribution. In the second case we put $\nu \sim \mathcal{GAL}_q(I_q, 1_{q, 10})$, i.e. $\nu$ has a $q$-variate generalized asymmetric Laplace distribution (c.f., Kozubowski et al. (2013)). Also, we put $q = 10$.

We compare the results for several values of $c \in \{0.1, 0.5, 0.8, 0.95\}$. The simulated data consists of $N = 10^4$ independent realizations which are used to fit the corresponding kernel density estimators with Gaussian density. The bandwith parameters are determined via cross-validation for every sample. The asymptotic distributions are simulated using the results of Theorems 2 and 3. The corresponding algorithm is given next:

a) generate $\nu = |\psi|$, where $\psi \sim N_q(0, I_q)$, or generate $\nu \sim \mathcal{GAL}_q(I_q, 1_{q, 10})$;

b) generate $l^T Sx$ by using the stochastic representation (9) obtained in the proof of Theorem 2, namely

$$ l^T Sx \overset{d}{=} \frac{\xi}{n-1} I^T \Sigma (y + B\nu) + \frac{\sqrt{\xi}}{n-1} ((y + B\nu)^T \Sigma (y + B\nu) I^T \Sigma l - (l^T \Sigma (y + B\nu))^2)^{1/2} z_0, $$

where $\xi \sim \chi^2_n$, $z_0 \sim N(0, 1)$, $y \sim N_p(\mu, \frac{1}{n} \Sigma)$; $\xi$, $z_0$, $y$, and $\nu$ are mutually independent.

b') generate $l^T S^{-1} \bar{\xi}$ by using the stochastic representation (21) obtained in the proof of Theorem 3, namely

$$ l^T S^{-1} \bar{\xi} \overset{d}{=} \tilde{\xi}^{-1} (n - 1) \left( l^T \Sigma^{-1} (\mu + B\nu) + \sqrt{l^T \Sigma^{-1} l} \sqrt{1 + \frac{\frac{p}{n} - 1 + \frac{1}{\eta}}{\frac{\frac{p}{n} - p + 1}{\eta}} \frac{z_0}{\sqrt{n}} } \right), $$

where $\tilde{\xi} \sim \chi^2_{n-p}$, $z_0 \sim N(0, 1)$, and $\eta \sim F_{p-1,n-p+1}(n \delta^2(\nu))$ with $\delta^2(\nu) = (\mu + B\nu)^T R_1 (\mu + B\nu)$, $R_1 = \Sigma^{-1} - I^T l l^T \Sigma^{-1} / I^T l I^T \Sigma^{-1} l$; $\tilde{\xi}$, $z_0$ and $(\eta, \nu)$ are mutually independent.

c) compute

$$ \sqrt{n \sigma^2_{\nu}} \left( l^T Sx - l^T \Sigma \mu_{\nu} \right) $$
and
\[ \sqrt{n} \tilde{\sigma}^{-1}_\nu \left( I^T S^{-1} x - \frac{1}{1 - c} I^T \Sigma^{-1} \mu_\nu \right) \]
where
\[
\begin{align*}
\mu_\nu &= \mu + B \nu \\
\sigma^2_\nu &= \left[ \mu^T_\nu \Sigma \mu_\nu + c ||\Sigma||_F^2 \right] I^T \Sigma I + (I^T \Sigma \mu_\nu)^2 \\
\tilde{\sigma}^2_\nu &= \frac{1}{(1 - c)^3} \left( 2 (I^T \Sigma^{-1} \mu_\nu)^2 + I^T \Sigma^{-1} I (1 + \delta^2(\nu)) \right)
\end{align*}
\]
with \( \delta^2(\nu) = \mu^T_\nu R I \mu_\nu \), \( R I = \Sigma^{-1} - \Sigma^{-1} I I^T \Sigma^{-1} / I^T \Sigma^{-1} I \).

d) repeat a)-c) \( N \) times.

It is remarkable that for generating \( I^T S x \) and \( I^T S^{-1} x \) only random variables from the standard distributions are need. Neither the data matrix \( X \) nor the sample covariance matrix \( S \) are used.

\[ \text{Figures 1-8} \]

In Figures 1-4 we present the results of simulations for the asymptotic distribution that is given in Theorem 2 while the asymptotic distribution as given in Theorem 3 is presented in Figures 5-8 for different values of \( c = \{0.1, 0.5, 0.8, 0.95\} \). The suggested asymptotic distributions are shown as a a dashed black line, while the standard normal distribution is a solid black line. All results demonstrate a good performance of both asymptotic distributions for all considered values of \( c \). Even in the extreme case \( c = 0.95 \) our asymptotic results seem to produce a quite reasonable approximation. Moreover, we observe a good robustness of our theoretical results for different distributions of \( \nu \). Also, we observe that all asymptotic distributions are slightly skewed to the right for the finite dimensions. This effect is even more significant in the case of the generalized asymmetric Laplace distribution. Nevertheless, the skewness disappears with growing dimension and sample size, i.e., the distribution becomes symmetric one and converges to its asymptotic counterpart.

5 Summary

In this paper we introduce the family of the matrix-variate generalized skew normal (MVGSN) distribution that generalizes a large number of the existing skew normal models. Under the
MVGSN distribution we derive the distributions of the sample mean vector and the sample covariance matrix. Moreover, we show that they are independently distributed. Furthermore, we derive the CLTs under high-dimensional asymptotic regime for the products of the sample (inverse) covariance matrix and the sample mean vector. In the numerical study, we document the good finite sample performance of both asymptotic distributions.

6 Appendix

Proof of Proposition 1.

Proof. Straightforward but tedious calculations give

\[
\begin{align*}
    f_N(Z) &= C^{-1} \int_{\mathbb{R}^n} f_{N_p,Y}(Y)(Z - B \nu^* | \nu = \nu^*) f_{N_q}(\xi, \Omega)(\nu^*) d \nu^* \\
    &= C^{-1} \frac{(2\pi)^{-(np+q)/2}}{|\Omega|^{n/2}} \left| \frac{1}{2} \left\{ -\frac{1}{2} \left( \nu^* - \xi \right)^T \Omega^{-1} (\nu^* - \xi) \right\} \right. \\
    &\times \exp \left\{ -\frac{1}{2} \left[ \operatorname{vec} (Z - \mu_1^T_n - B \nu^* 1_n^T) (1_n \otimes \Sigma)^{-1} \operatorname{vec} (Z - \mu_1^T_n - B \nu^* 1_n^T) \right] \left( \nu^* - \xi \right) \right\} \\
    &= C^{-1} \frac{(2\pi)^{-(np+q)/2}}{|\Omega|^{n/2}} \left| \frac{1}{2} \left[ \operatorname{vec} (Z - \mu_1^T_n)^T (1_n \otimes \Sigma)^{-1} \operatorname{vec} (Z - \mu_1^T_n) + \xi^T \Omega^{-1} \xi \right] \right. \\
    &\times \exp \left\{ \frac{1}{2} \left[ (\operatorname{Evec}(Z - \mu_1^T_n) + \Omega^{-1} \xi)^T D (\operatorname{Evec}(Z - \mu_1^T_n) + \Omega^{-1} \xi) \right] \right\} \\
    &\times \int_{\mathbb{R}^n} \exp \left\{ -\frac{1}{2} \left[ \left( \nu^* - D (\operatorname{Evec}(Z - \mu_1^T_n) + \Omega^{-1} \xi) \right)^T \right. \\
    &\times \left. D^{-1} (\nu^* - D (\operatorname{Evec}(Z - \mu_1^T_n) + \Omega^{-1} \xi)) \right\} dv^* \\
    &= C^{-1} \frac{|F|^{1/2}|D|^{1/2}}{|\Omega|^{n/2}} \exp \left\{ -\frac{1}{2} \left[ \xi^T \Omega^{-1} (-D + \Omega - D \Sigma^{-1} D)^{-1} \xi \right] \right\} \\
    &\times \Phi_q (0; -D \Sigma^{-1} D \Phi_p (\operatorname{vec}(Z - \mu_1^T_n); FE^T D \Omega^{-1} \xi, F) \\
    &= C^{-1} \frac{|F|^{1/2}|D|^{1/2}}{|\Omega|^{n/2}} \exp \left\{ -\frac{1}{2} \left[ \xi^T \Omega^{-1} (-D + \Omega - D \Sigma^{-1} D)^{-1} \xi \right] \right\} .
\end{align*}
\]

where \( D = (nB^T \Sigma^{-1} B + \Omega^{-1})^{-1}, E = 1_n^T \otimes B^T \Sigma^{-1}, F = (1_n \otimes \Sigma^{-1} - B^T DE)^{-1}, \) and

\[
C^{-1} = C^{-1} \frac{|F|^{1/2}|D|^{1/2}}{|\Omega|^{n/2}} \exp \left\{ -\frac{1}{2} \left[ \xi^T \Omega^{-1} (-D + \Omega - D \Sigma^{-1} D)^{-1} \xi \right] \right\} .
\]

Figure 5: The kernel density estimator of the asymptotic distribution as given in Theorem 3 for $c = 0.1$. 

25
(a) $p = 250, n = 500, \nu \sim T N_q(0, I_q)$.

(b) $p = 500, n = 1000, \nu \sim T N_q(0, I_q)$.

(c) $p = 250, n = 500, \nu \sim \mathcal{G} A L_q(I_q, I_q, 10)$.

(d) $p = 500, n = 1000, \nu \sim \mathcal{G} A L_q(1_q, I_q, 10)$.

Figure 6: The kernel density estimator of the asymptotic distribution as given in Theorem 3 for $c = 0.5$. 
(a) \( p = 400, n = 500, \nu \sim \mathcal{N}_q(0, I_q) \).

(b) \( p = 800, n = 1000, \nu \sim \mathcal{N}_q(0, I_q) \).

(c) \( p = 400, n = 500, \nu \sim \mathcal{GAL}_q(1_q, I_q, 10) \).

(d) \( p = 800, n = 1000, \nu \sim \mathcal{GAL}_q(1_q, I_q, 10) \).

Figure 7: The kernel density estimator of the asymptotic distribution as given in Theorem 3 for \( c = 0.8 \).
Figure 8: The kernel density estimator of the asymptotic distribution as given in Theorem 3 for $c = 0.95$.

(a) $p = 475, n = 500, \nu \sim T\mathcal{N}_q(0, I_q)$.

(b) $p = 950, n = 1000, \nu \sim T\mathcal{N}_q(0, I_q)$.

(c) $p = 475, n = 500, \nu \sim G\mathcal{AL}_q(1_q, I_q, 10)$.

(d) $p = 950, n = 1000, \nu \sim G\mathcal{AL}_q(1_q, I_q, 10)$.
